#### Session 2: Introduction to R Programming

R for Stata Users

Luiza Andrade, Marc-Andrea Fiorina, Rob Marty, Rony Rodriguez-Ramirez, Luis Eduardo San Martin, Leonardo Viotti The World Bank | WB Github

March 2023

#### Table of contents

- 1. Introduction
- 2. Initial settings
- 3. File paths
- 4. Using packages
- 5. Functions inception
- 6. Mapping and iterations
- 7. Custom functions
- 8. Appendix

## Introduction

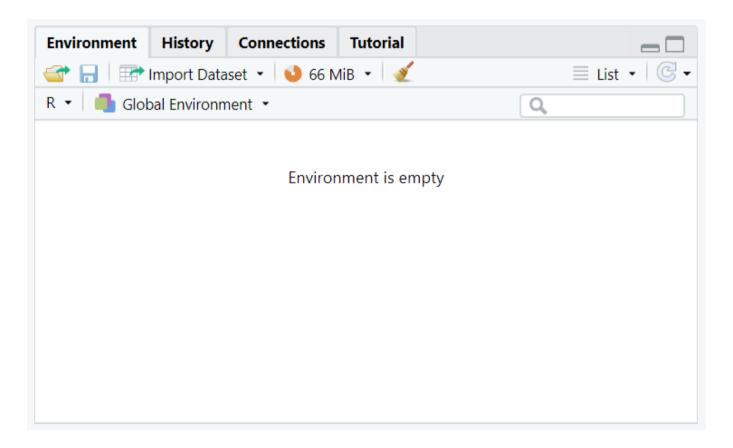

#### What this session is about

- In the first session, you learned how to work with R
- You are probably eager to start programming in R by now
- But before you start, we recommend learning how to write R code that will be **reproducible, efficient, intelligible and easy to navigate**
- Indeed, that's what this session is about!

#### What this session is about

- We will cover common coding practices in R so that you can make **the most efficient use** for it
- We will also discuss some styling conventions to make your code **readable and reproducible**
- This will give you a solid foundation to write code in R and hopefully you'll be able to skip some painful steps of the "getting-your-hands-dirty" learning approach

- Let's start by opening RStudio or by closing and opening it again
- Notice two things:
  - 1. Your environment is *probably* empty (it's okay if it's not)

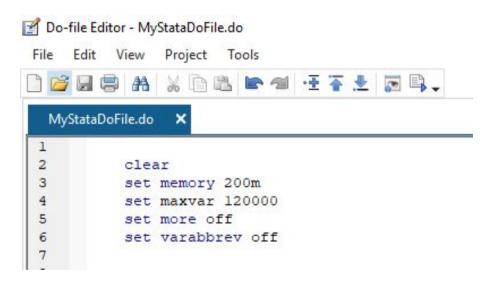

- Let's start by opening RStudio or by closing and opening it again
- Notice two things:
  - 1. Your environment is *probably* empty (it's OK if it's not)
  - 2. Go to the **Console** panel and use the up and down keys to navigate through previously executed commands. They are saved by default in a file named . **Rhistory** that you might have noticed

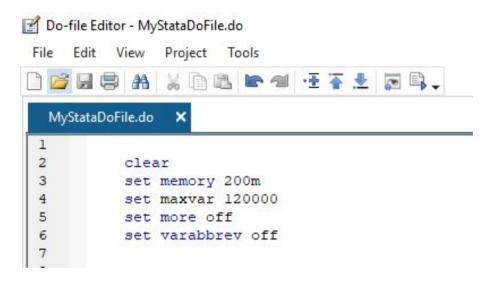

Name	Date modified	Туре
DataWork	10/27/2022 10:36 AM	File folder
learnr	7/19/2022 4:47 PM	File folder
Presentations	3/19/2023 12:11 PM	File folder
	7/19/2022 4:47 PM	GITIGNORE File
.Rhistory	5/26/2022 1:27 PM	RHISTORY File
■ dime-r-training.Rproj	5/26/2022 9:10 AM	R Project
LICENSE	12/15/2020 2:53 PM	File
® README.md	3/14/2023 4:24 PM	MD File

- Let's start by opening RStudio or by closing and opening it again
- Notice two things:
  - 1. Your environment is *probably* empty (it's OK if it's not)
  - 2. Go to the **Console** panel and use the up and down keys to navigate through previously executed commands. They are saved by default in a file named . **Rhistory** that you might have noticed
- We'd usually want these two things -- an **empty environment** and the **history of commands** executed in previous sessions -- to be present every time we open a new RStudio session

Have you ever seen these lines of code before?

Have you ever seen these lines of code before?

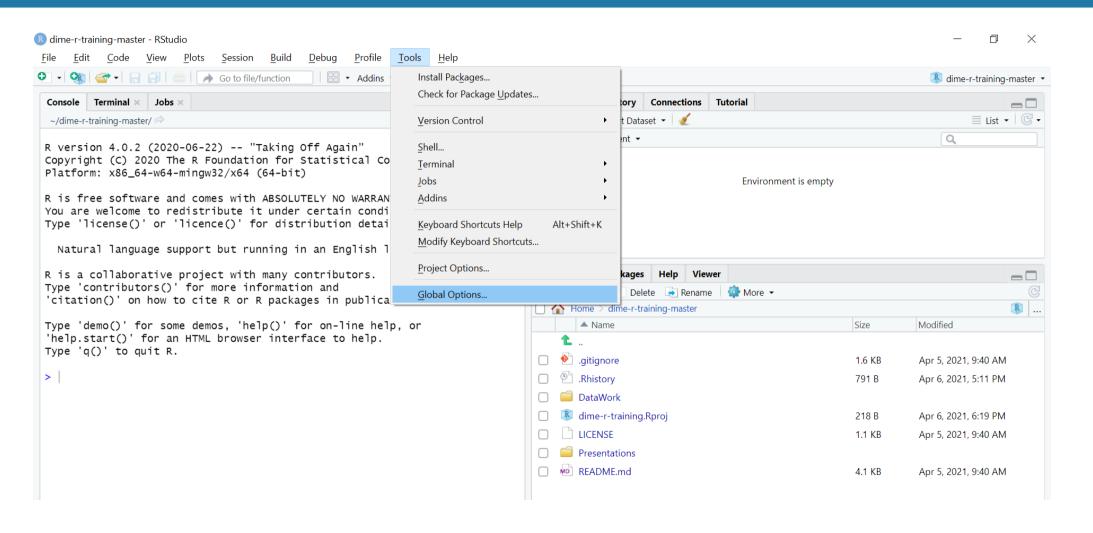

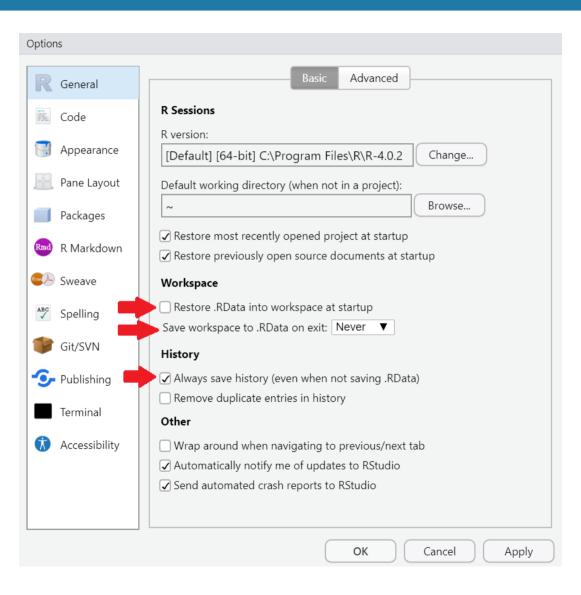

- We don't need to set the memory or the maximum number of variables in R
- The equivalent of set more off is the default
- The equivalent of clear all is not a default setting, but we'll change that in exercise 1

#### Exercise 1 (() 1 min)

After this, you'll never have to use the equivalent of clear all

- 1. Go to Tools > Global Options...
- 2. In the **General** tab, make sure the following options are set:
  - Un-check Restore .RData into workspace at startup
  - For Save workspace to .RData on exit, select Never
  - Make sure Always save history (even when not saving .RData) is checked
- 3. Now restart RStudio

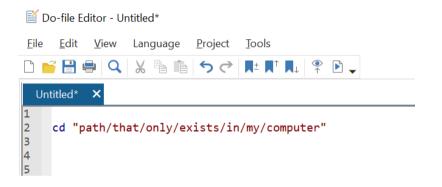

# File paths

### File paths

• What about working directories? We usually do something like this every time we start a new script in Stata:

• The direct equivalent to cd in R is this command:

```
setwd("your/path")
```

• However, we recommend not using it unless it's absolutely necessary (never, if possible)

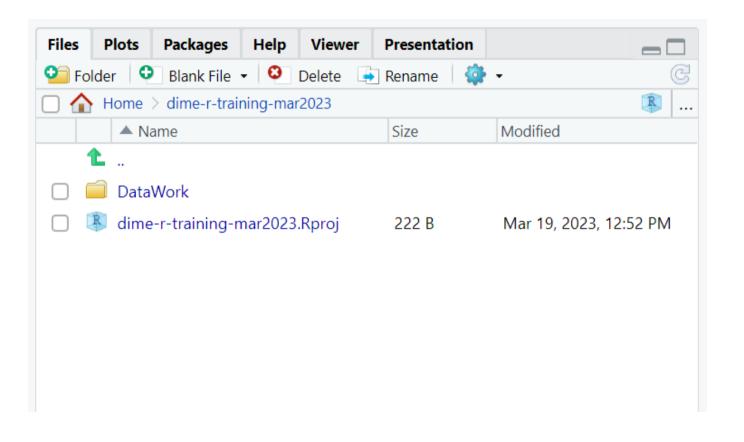

- Instead, you should use RStudio projects and the here library
- RStudio projects let you "bind" your project files to a root directory, regardless of the path to it
- This is crucial because it allows smooth interoperability between different computers where the exact path to the project root directory differs
- Additionally, each RStudio project you work on keeps their own history of commands!

**Important:** We won't get into the specifics of directory organization here, but we'll assume that all the files you use for a specific project (data, scripts, and outputs) reside in the same project directory. We'll call this the **working directory**.

#### Exercise 2 (() 3 min)

- 1. Create a folder named dime-r-training-mar2023 in your preferred location in your computer
- 2. Go to https://osf.io/86g3b/ and download the file in: R for Stata Users 2023 March > Data > DataWork.zip
- 3. Unzip DataWork.zip in the folder dime-r-training-mar2023
- 4. On RStudio, select File > New Project...
- 5. Select Existing Directory
- 6. Browse to the location of dime-r-training-mar2023 and select Create Project

## The here library

- here locates files relative to your project root
- It uses the root project directory to build paths to files easily
- It allows for interoperability between different computers where the absolute path to the same file is not the same

## Usage of here

• Load here

```
install.packages("here") # install first if you don't have it
library(here)
```

- Now you'll be able to use here() to point the location of every file relative to your project root
  - For example, to load a csv file located in: C:/WBG/project-root-name/data/raw/data-file.csv, you should use:

```
path <- here("data", "raw", "data-file.csv")
df <- read.csv(path)</pre>
```

#### Notes:

- Your project root is the directory that contains the .Rproj file
- The result of here() is an absolute path that points to a file or folder location in your computer

## File paths

#### Exercise 3 (() 3 min)

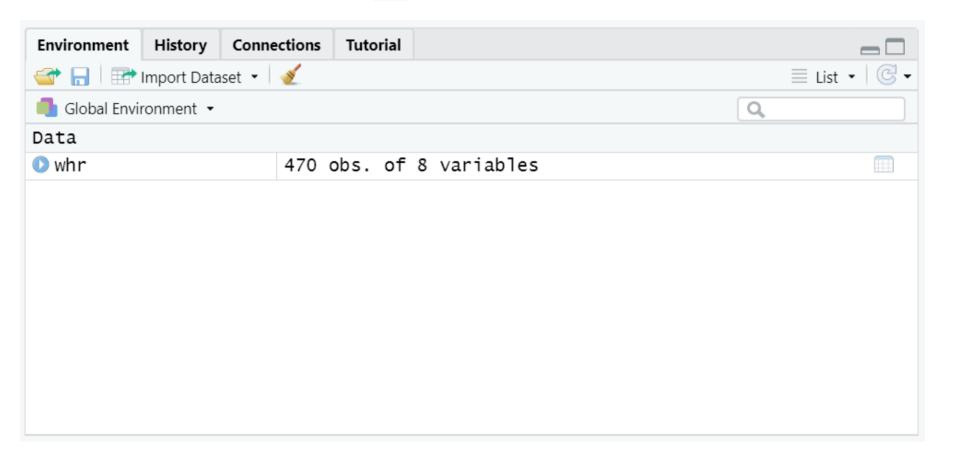

- 1. Load here and read the .csv file in DataWork/DataSets/Final/whr\_panel.csv using here()
  - Use the function read.csv() to load the file. The argument for read.csv() is the result of here()
  - Remember to assign the dataframe you're reading to an object. You can call it whr as we did yesterday

## File paths

```
library(here)
whr <- read.csv(here("DataWork", "DataSets", "Final", "whr_panel.csv"))</pre>
```

## RStudio projects and here

If you did the exercise correctly, you should see the whr dataframe listed in the Environment panel

# Using packages

## Packages

- Since there is a lot of people developing for R, it can have many different functionalities
- To make it simpler, these functionalities are bundled into packages
- A package is just a unit of shareable code

#### Packages

- Packages may contain new functions, but also more complex functionalities, such as a Graphic User Interface (GUI) or settings for parallel processing (similar to Stata MP)
- They are usually shared through R's official repository CRAN (19,000+ packages reviewed and tested)
- There are many other online sources such as GitHub, but it's important to be careful, as these probably haven't gone through a review process as rigorous as those in CRAN

#### Packages

• To install and use packages you can either do it with the user interface or by the command prompt.

• You only have to install a package once, but you have to load them every new session.

## Using packages

#### Exercise 4 ( ( 1 min)

- 1. Load the packages dplyr and purrr in part 1 of your script using library(dplyr) and library(purrr)
- 2. Run your script

#### Warnings vs errors

What if this happens?

```
> library(dplyr)
Attaching package: 'dplyr'
The following objects are masked from 'package:stats':
    filter, lag
The following objects are masked from 'package:base':
    intersect, setdiff, setequal, union
Warning message:
package 'dplyr' was built under R version 4.2.2
```

## Warnings vs errors

R has two types of error messages, warnings and actual errors:

- Errors break your code, usually preventing it from running
- Warnings your code kept running, but R wants you to be aware of something that might be a problem later

RStudio's default is to print warning messages, but not to stop the code at the lines where they occur. You can configure R to stop at warnings if you want.

## **Functions inception**

#### A function inside a function

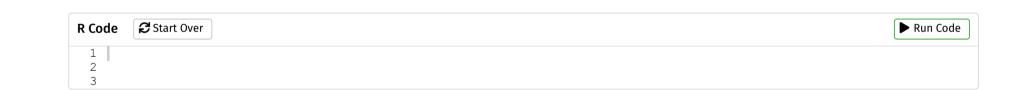

- In R, you can write one function inside another
- In fact, you have already done this several times in this course
- Here's an example:

#### A function inside a function

```
# Print the summary of the logarithm of the happiness score

## The long way:
log_score <- log(whr$happiness_score)
summary(log_score)

# The shortcut
summary(log(whr$happiness_score))</pre>
```

#### A function inside a function

- This is a simple example of **metaprogramming** (that's the real name of this technique) and may seem trivial, but it's not
- For starters, you can't do it in Stata!

### A function inside a function

variable log not found
r(111);
```

### A function inside a function

- Metaprogramming is a **very powerful technique**, as you will soon see
- It's **also a common source of error**, as you can only use one function inside the other if the output of the inner function can be taken as the input of the outer function
- It can also get quite tricky to follow what a line of code with multiple functions inceptions is doing

# Piping

- Ever heard of piping? It's this: %>%
- Piping is a way of doing metaprogramming
- The actual meaning of the pipes is: Pipes take the **output** of the function at the left and pass it as the **first argument** of the function at the right
- The advantages of using piping is that it allows to have a cleaner division of successively applied functions in R code, drastically improving code readability

# Piping

```
# 1: Doing it the long way ------
log_score <- log(whr$happy_score)
mean(log_score)

# 2: Shortcut to get to the same place -----
mean(log(whr$happy_score))

# 3: Now with pipes ------
whr$happy_score %>%
log() %>%
mean()
```

#### Just remember:

- x %>% f() is the same as f(x)
- x %>% f() %>% g() is the same as g(f(x))

# Mapping and iterations

## Iterations in R

- In Stata, we use **for** loops very frequently
- In R, the syntax of for loops is this:

```
for (number in 1:3) {
    print(number)
}
```

```
## [1] 1
## [1] 2
## [1] 3
```

## Map

- R, however, has a set of functions that allows users to loop through an object **in a more efficient way**, without using explicit loops
- In this training we'll introduce map(). It is a function part of purrr, a package that contains tools for functional programming
- Also, in case you have not noticed yet: **R is vectorized!** this means that many operations are applied element-wise by default so you don't have to code loops to apply them to each element of a vector or dataframe

## Map

- To use map(), you need to load the package purrr
- The basic syntax of map() is:

map(X, function, ...): applies function to each of the elements of X. If X is a dataframe then function is applied column-wise while if it's a vector or a list it is applied item-wise. The output of map() is always a list with the results.

- X: a dataframe, matrix or vector the function will be applied to
- function: the name of the function you want to apply to each of the elements of X

## Map

```
# Round the values of the following vector

x <- c(1.2, 2.5, 9.1, 5.8)

x %>% map(round) # Rounding the vector elements (same as map(x, round))

round(x) # since R is vectorized, this also works
```

- When looping, you repeat the same operation over a set of items
- map(), instead, takes all your elements at once and applies an operation to them simultaneously
- The difference is like this:
  - Imagine you ask a yes/no question to a group of people
  - You can collect the answers by asking each one of them individually -- this is looping
  - Otherwise, you can ask them to raise their hands and collect all answers at once -- this is map()

- The output of a loop is the regular output of the operation you're repeating, times the number of iterations you did
- The output of map() will be always a list
- When it comes to code clarity, map() has a few advantages:
  - Loops often have side effect results, like a temporary variable that stays in the environment after the loop finishes
  - map() often involves less lines of code than loops

### Exercise 5: Looping over a dataframe (© 3 min)

• Create a toy dataframe of 50,000 columns and 400 observations using this code

```
df <- data.frame(replicate(50000, sample(1:100, 400, replace=TRUE)))

• Create an empty vector named col_means_loop where you will store column means with this code:</pre>
```

col\_means\_loop <- c()</li>
 Loop over every column to get the column means and store them in the vector

```
for (column in df) {
   ....
}
```

- Inside the loop:
  - Use mean() to get each column mean
  - Use append() to add a new mean to the vector: col\_means\_loop <- append(col\_means\_loop, new\_mean)</li>

The solution is this:

```
df <- data.frame(replicate(50000, sample(1:100, 400, replace=TRUE)))

col_means_loop <- c()

for (column in df){
   col_means_loop <- append(col_means_loop, mean(column))
}</pre>
```

```
Exercise 6: Now use map() (() 1 min)

1. Use map() to produce a list with the means of the columns of df

2. Store the result in a list named col_means_map
```

#### Hints:

- Remember the syntax of map(): map(X, function\_name)
- The function name inside map() shouldn't have parentheses next to it (i.e.: mean instead of mean())

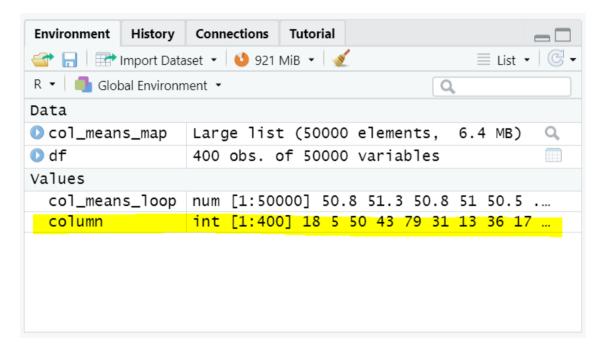

Compare the syntax of the solutions of both exercises:

```
# Dataframe creation
df <- data.frame(replicate(50000, sample(1:100, 400, replace=TRUE)))
# Loop exercise
col_means_loop <- c()

for (col in df){
    col_means_loop <- append(col_means_loop, mean(col))
}
# Map exercise
col_means_map <- map(df, mean)</pre>
```

Do you remember which one ran faster?

Also, remember we said that loops produce side effects?

- map() looks nice, doesn't it?
- But what about cases when it's impossible to implement the operations I want to apply in only one function? Do I have to use for loops then?
- Not at all! Let's get to the next section for those cases.

# Writing your own functions

- As we have said several times, **R** is super flexible
- One example of that is that it's **super easy and quick to create custom functions**
- Here's how:

```
square <- function(x) {
  y <- x ^ 2
  return(y)
}</pre>
```

#### Exercise 7 ( 2 min)

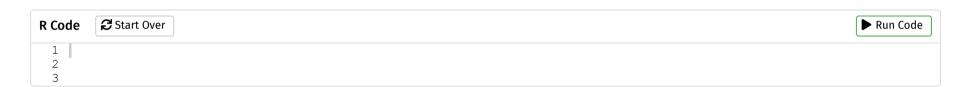

Create a function named **zscore** that standardizes the values of a vector.

#### **Hints:**

- The command to obtain the mean of a vector is mean(x)
- The command to get the SD of a vector is sd(x)
- R is vectorized: you can operate vectors and numbers directly and the result will be a vector
- Don't forget to include the argument na.rm = TRUE in mean() and sd()
- Recall the syntax of custom functions in R:

```
function_name <- function(input) {
  output <- operation(input)
  return(output)
}</pre>
```

```
zscore <- function(x) {
   mean <- mean(x, na.rm = TRUE)
   sd <- sd(x, na.rm = TRUE)
   z <- (x - mean)/sd
   return(z)
}</pre>
```

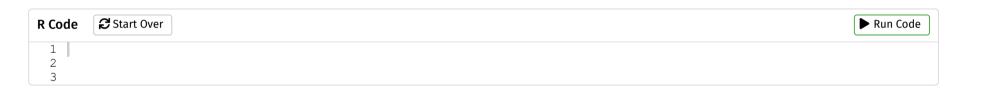

#### Exercise 8

- 1. Subselect the columns health\_life\_expectancy and freedom in whr
  - Use dplyr's select() for this, as in: whr %>% select(freedom, happiness\_score)
- 2. Use map() combined with the zscore function to get the z-score of these two columns and assign the resulting list to an object named z\_scores
- 3. Use list indexing on <a href="mailto:z\_scores">z\_scores</a> to generate two new columns in <a href="whr">whr</a> with the standardized values of <a href="health\_life\_expectancy">health\_life\_expectancy</a> and <a href="mailto:freedom">freedom</a>

#### **Hints:**

- Don't use parenthesis next to the function name we're using map() with
- Use double brackets instead of single brackets or the symbol \$\frac{1}{2}\$ to index the elements of a list

```
z_scores <- whr %>%
  select(health_life_expectancy, freedom) %>%
  map(zscore)
whr$hle_st <- z_scores[[1]]
whr$freedom_st <- z_scores[[2]]</pre>
```

# Thank you!

# Appendix

# Appendix - Rhistory and RData

- .Rhistory automatically stores the commands entered in the console
- RData stores the objects in your environment only if you save your workspace, and loads them again in the next RStudio session
- Both files are stored in the working directory where your RStudio session started

# Appendix - More on packages

Once a package is loaded, you can use its features and functions. Here's a list of some useful packages:

- Rcmdr easy to use GUI
- swirl an interactive learning environment for R and statistics.
- ggplot2 beautiful and versatile graphics (the syntax is a pain, though)
- stargazer awesome latex regression and summary statistics tables
- foreign reads .dta and other formats from inferior statistical software
- **zoo** time series and panel data manipulation useful functions
- data.table some functions to deal with huge dataframes
- sp and rgeos spatial analysis
- multiwayvcov and sandwich clustered and robust standard errors
- RODBC, RMySQL, RPostgresSQL, RSQLite For relational databases and using SQL in R.

# Appendix - Git

Git is a version-control system for tracking changes in code and other text files. It is a great resource to include in your work flow.

We didn't cover it here because of time constraints, but below are some useful links, and DIME Analytics provides trainings on Git and GitHub, so keep an eye out for them.

- DIME Analytics git page: https://worldbank.github.io/dimeanalytics/git/
- A Quick Introduction to Version Control with Git and GitHub: https://journals.plos.org/ploscompbiol/article? id=10.1371/journal.pcbi.1004668

# Appendix - More on R projects

If you want to learn more about them, we recommend starting here: https://r4ds.had.co.nz/workflow-projects.html

# Appendix - More on folder management

- A discussion of folder structure and data managament can be found here: https://dimewiki.worldbank.org/wiki/DataWork\_Folder
- For a broader discussion of data management, go to https://dimewiki.worldbank.org/wiki/Data\_Management

# Appendix - Column extraction operators

- Remember the use of \$ to extract columns from a dataframe?
- Other than \$, we can also use double brackets to extract the column of a dataframe:

```
# With $:
whr$year

# With [[]]:
whr[["year"]] # Notice the use of double quotes
```

# Appendix - Column extraction operators:

What's the key difference between them?

## [1] 2015 2015 2015 2015 2015 2015

Well, [[]] lets us use other objects to refer to column names, while \$ doesn't

```
col_name <- "year"
head(whr$col_name) # this returns a NULL object because no column has the name "col_name" in whr

## Warning: Unknown or uninitialised column: `col_name`.

## NULL

col_name <- "year"
head(whr[[col_name]])</pre>
```

## Appendix - Column extraction operators:

This difference is key because we can use [[]] to loop through column names, while this is not directly possible with \$.

```
# Printing the first observation of every column of whr
for (col in colnames(whr)) {
   whr[[col]] %>%
   head(1) %>%
   print()
}
```

```
## [1] "Switzerland"
## [1] "Western Europe"
## [1] 2015
## [1] 1
## [1] 7.587
## [1] 1.39651
## [1] 0.94143
## [1] 0.66557
```

# Appendix - Apply

- Apart from purrr's map(), base R also has a set of functions that allows users to apply a function to a number of objects without using explicit loops
- They're called apply and there are many of them, with different use cases
- If you look for the apply help file, you can see all of them
- We'll show only two of them, sapply and apply

# Appendix - Apply

• The syntax of sapply() is:

```
sapply(X, FUN, ...)
```

- Its main arguments are:
  - X: a dataframe, matrix or vector the function will be applied to
  - **FUN:** the function you want to apply
- sapply() applies the function (FUN) to all the elements of X. If X is a dataframe then the function is applied columnwise, while if it's a vector or a list it is applied item-wise
- The output of sapply() is usually a vector with the results, but it can be a matrix if the results have more than one dimension

```
# A for loop in R
for (number in c(1.2, 2.5)) {
   print(round(number))
}

# A much more elegant option
sapply(c(1.2, 2.5), round)
```

```
# Printing the first observation of every column of whr
for (col in names(whr)) {
  print(head(whr[[col]], 1))
} # Option 1

sapply(whr, head, 1) # A more elegant and efficient option
```

• A more general version of sapply() is the apply() function. This is its syntax:

```
apply(X, MARGIN, FUN, ...)
```

- Arguments:
  - X: a dataframe (or matrix) the function will be applied to
  - MARGIN: 1 to apply the function to all rows or 2 to apply the function to all columns
  - **FUN:** the function you want to apply
- apply() applies a function (FUN) to all columns or rows of matrix (X). A value of 1 in MARGIN indicates that the funcion should be applied row-wise, while 2 indicates columns

```
matrix <- matrix(c(1, 24, 9, 6, 9, 4, 2, 74, 2), nrow = 3) # Defining a matrix
apply(matrix, 1, mean) # row means
apply(matrix, 2, mean) # column means</pre>
```

## Appendix - Assignment 1

#### Exercise: Get the row max

- 1. Select the columns freedom and happiness\_score of whr
- 2. Use apply() to get the row max between these two columns, for every row
- Hints:
  - Remember the syntax of apply(): apply(X, MARGIN, FUN)
  - A value of 1 for MARGIN indicates that the function must applied row-wise
  - The function to get the maximum over a set of number is max

#### Solution:

```
whr %>%
  select(freedom, happiness_score) %>%
  apply(1, max)
```

## **Appendix - Commenting**

• To comment a line, write # as its first character

```
# This is a comment
print("But this part is not")
```

• You can also add # halfway through a line to comment whatever comes after it

```
print("This part is not a comment") # And this is a comment
```

- In Stata, you can use /\* and \*/ to comment in the middle of a line's code. That is not possible in R: everything that comes after # will always be a comment
- To comment a selection of lines, press Ctrl + Shift + C

## Appendix - Assignment 2

#### Exercise

- 1. In your script panel, select all the lines of your script
- 2. Use the keyboard shortcut to comment these lines.
  - Shortcut: Ctrl + Shift + C
- 3. Use the keyboard shortcut to comment these lines again. What happened?

### Appendix - Document outline

- RStudio allows you to **create an interactive index** for your scripts
- To add a section to your code, create a commented line with the title of your section and add at least 4 trailing dashes ( --- ), pound signs ( #### ) or equal signs ( ==== ) after it

#### Appendix - Document outline

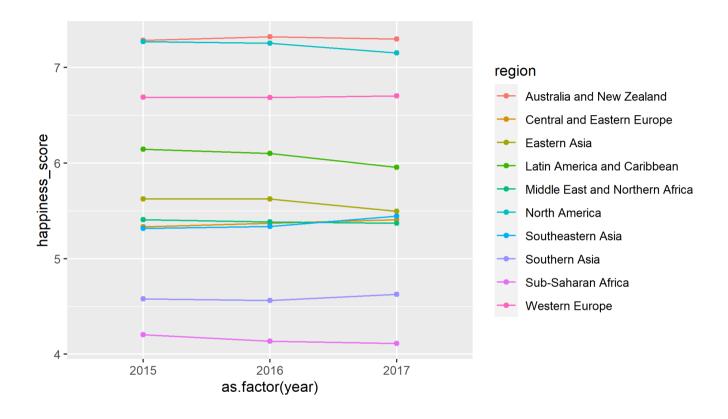

- The outline can be accessed by clicking on the button on the top right corner of the script window. You can use it to jump from one section to another
- You can also use the keyboard shortcuts Alt + L (Cmd + Option + L on Mac) and Alt + Shift + L to collapse and expand sections

```
exercises.R ×

| Source on Save | Source
```

```
# Here's some code
annualHappy_reg <- aggregate(happy_score ~ year + region, data = whr, FUN = mean)
ggplot(annualHappy_reg,aes(y = happy_score,x = as.factor(year), color = region, group = region)) +
geom_line() + geom_point()</pre>
```

```
# Here's the same code
annualHappy reg <-
  aggregate(happiness_score ~ year + region,
            data = whr,
            FUN = mean)
ggplot(annualHappy_reg,
       aes(y = happiness_score,
           x = as.factor(year),
           color = region,
           group = region)) +
geom_line() +
geom_point()
```

- R understands what unindented code says, but it can be quite difficult for a human being to read it
- On the other hand, white space does not have a special meaning for R, so it will understand code that is more readable for a human being

- Indentation in R looks different than in Stata:
  - To indent a whole line, you can select that line and press Tab
  - To unindent a whole line, you can select that line and press **Shift + Tab**
  - However, this will not always work for different parts of a code in the same line
- In R, we typically don't introduce white space manually
- It's rather introduced by RStudio for us

## Appendix - Assignment 3

#### Exercise

To see an example of how indenting works in RStudio, let's use an example with map():

```
# An elegant "loop" in R map(c(1.2, 2.5, 9.1, 5.8), round)
```

- 1. Add a line between the two arguments of the function (the vector of numbers and round)
- 2. Now add a line between the numbers in the vector.

Note that RStudio formats the different arguments of the function differently:

## Appendix - Exploring a dataframe

#### Some useful functions:

- View(): opens a visualization of the dataframe
- class(): reports object type or type of data stored
- dim(): reports the size of each one of an object's dimension
- names(): returns the variable names of a dataframe
- str(): general information about the structure of an R object
- **summary():** summary information about the variables in a dataframe
- head(): shows the first few observations in the dataframe
- tail(): shows the last few observations in the dataframe
